

# Combining Relevant Data in Excel

## Objectives

Data Analytics often requires data from multiple sources. Keeping this data in sync with its various sources can be difficult. In this activity, you will link data in one worksheet to data contained in multiple other worksheets. You will use the Workbook Links feature of Excel to create external links and ensure that data in the multiple worksheets remains synchronized.

External references between Excel workbooks are especially useful when it's not practical to keep large worksheet models together in the same workbook. You can use these references to:

**Consolidate data from several workbooks** - Workbooks that contain data from several years, departments, or products can be linked. You can perform summary or other functions on the data to create reports or graphs.

Create different subsets of your data - You can use external references to create reports that contain only relevant data, not the entire contents of the individual workbooks. - You can use external references to create reports that contain only relevant data, not the entire contents of the individual workbooks.

**Split complex data into separate workbooks** – Because you can link to portions of the worksheets, or create summaries, you can use multiple workbooks to store smaller parts of the data, instead of having it all in one giant workbook.

### Part 1: Link Multiple Worksheets

### Part 2: Refreshing Data in Multiple Worksheets

## Background / Scenario

The bicycle shop keeps sales data in separate worksheets, one for each year. They would like you to perform data analysis on their sales records. In this lab, you will create a consolidated spreadsheet containing external links to each year's data.

## Required Resources

- Microsoft 365 Excel on Office.com
- Microsoft 365 OneDrive

The Worksheet Links function enables you to update data when the original data changes, by refreshing the linked data.

### Step 1: Use Excel Functions to Summarize Data from Multiple Worksheets

- Add a new worksheet (Sheet3) to the BikeSales\_Consolidated workbook.
- In **Row 1**, create two column headings: **2021 Average Cost** and **2021 Average Revenue**.
- In Cell **A2**, type (do not copy and paste) **=AVERAGE(** Then, with the cursor next to the open parenthesis, click on the browser tab that contains the BikeSales\_2021 worksheet.
- Select the range of cells **Q2:Q14**. Return to the **BikeSales\_Consolidated** workbook and press **ENTER**.

What is the value in Cell A2 after the spreadsheets are linked?

Answer Area

**\$26,479.30769**

- Place the cursor in cell B2. Repeat the steps to return the average of 2021 revenue (**Column R** in the **BikeSales\_2021** Worksheet).

What is the value in Cell B2 after the spreadsheets are linked?

Answer Area

**\$43,764.31**

### Step 2: Update Data in the Source Spreadsheet

Now that the spreadsheets are linked, updates to the data in the source sheet can be automatically updated in the consolidated sheet.

- Open the browser tab containing the **BikeSales\_2021** worksheet.
- Update the value in cell **Q6** to be \$30,000.00. Return to the **BikeSales\_Consolidated** worksheet **Sheet3**.
- Select Data > Workbook Links (in the Queries & Connections section) in the tool bar. A window opens on the side of the screen with a list of workbooks linked to this worksheet.

- Click the circular refresh icon next to the **BikeSales\_2021.xlsx** listing.

What happens to the average values in cell A2?

Answer Area

\$28,495.92

- e. Open Sheet1 that contains the linked data from BikeSales\_2021 and press the refresh button in the Workbook Links panel again.

What is the value in cell Q6?

Answer Area

\$30,000

## Reflection

What are some situations in which you would want to use Workbook links to keep data synchronized between workbooks?

This function in excel is very useful because it enables us to link workbooks in separate sheets and update it accordingly. This makes it convenient because we don't have to cramp every one of our data and make it less confusing.
